

Drugstore Beetle, *Stegobium paniceum* (L.) (Insecta: Coleoptera: Anobiidae)¹

Brian J. Cabrera²

Introduction

There are over 1000 described species of anobiids. Many are wood borers, but two, the drugstore beetle, *Stegobium paniceum* (L.) (known in the United Kingdom as the biscuit beetle) and the cigarette beetle, *Lasioderma serricorne* (F.) (also known as the tobacco beetle), attack stored products. Stored product pests cause tremendous damage and economic losses to post-harvest and stored grains and seeds, packaged food products, and animal and plant-derived items and products. Besides causing direct damage by feeding, they elicit disgust, annoyance, and anger in many of those who find them infesting these products.

Distribution

Drugstore beetles have a worldwide distribution, but are more abundant in warmer regions or in heated structures in more temperate climates. They are less abundant in the tropics than the cigarette beetle.

Description and Identification

Adults

The beetles are cylindrical, 2.25 to 3.5 mm (1/10 to 1/7 inch) long, and are a uniform brown to reddish brown. They have longitudinal rows of fine hairs on the elytra (wing covers). Drugstore beetles are similar in appearance to the [cigarette beetle](#); however, two physical characters can

be used to tell the difference between them. The antennae of the cigarette beetle are serrated (like the teeth on a saw) while the antennae of the drugstore beetle are not and end in a 3-segmented club. The other difference is that the elytra (wing covers) of the drugstore beetle have rows of pits

giving them a striated (lined) appearance while those of the cigarette beetle are smooth.

Larvae

Small, white grubs; the later instars are scarab-like. They are similar to cigarette beetle larvae, but have shorter hairs and the marking on the head ends in a straight line across the frons just above the mouthparts.

Life History

Females lay up to 75 eggs in the food or substrate. The larval period ranges from four to 20 weeks. Larvae tunnel through the substrate and when fully grown build a cocoon and pupate. Pupation takes from 12 to 18 days. Adult females live approximately 13 to 65 days. The entire life cycle is generally less than two months but can be as long as seven months. The duration of the life cycle is highly dependent on the temperature and food source. Development occurs between 60 to 93°F (~15 to 34°C) but is optimal at about 85°F (~30°C) and 60 to 90% relative humidity.

Pest Status

The drugstore beetle attacks such a wide variety of foods and material that one anonymous quote states that it “eats anything but cast iron.” It gets its name from its habit of feeding on prescription drugs. It also feeds on flours, dry mixes, breads, cookies, chocolates and other sweets, and spices. Non-food material includes wool, hair, leather, horn, and museum specimens. It is found in pigeon nests and is known to bore into books, wooden objects, and, in some cases, tin or aluminum foil and lead sheets. Larval feeding accounts for the greatest amount of damage. Museum and herbarium specimens are vulnerable to attack. Slight damage and contamination can ruin these valuable and priceless items. Drugstore beetles harbor symbiotic yeasts that produce B vitamins. The yeasts are deposited on the eggs as they pass through the oviduct and are consumed by the larvae during egg hatch. These yeasts enable the drugstore beetle to feed and survive on many foods and other items of poor nutritional quality.

Management

Home

Preventing and controlling drugstore beetle infestations is relatively simple: Insecticides should be used only as a last resort. Locating the source or sources of infestation is the first and most important step. Heavily infested items should be wrapped in heavy plastic, taken outside and thrown away. All food containers and items should be checked for infestation. Items can be placed in the refrigerator or freezer (16 days at 36°F, 7 days at 25°F or 32°F for four to seven days) to kill all stages. Place the items in a plastic bag to reduce condensation problems during thawing. Heating small quantities of infested material (190°F for one hour, 120°F for 16 to 24 hours) in an oven is also effective. Uninfested items can be cold- or heat-treated to ensure that any undetected stages are killed. To prevent reinfestation, clean up spilled flour, mixes, crumbs, etc. and thoroughly

vacuum and clean areas where the contaminated items were stored. Store foods in airtight glass, metal or plastic containers. Clear containers make it easier to check for infestation. Chemical treatment using commercially available insecticides or insect growth regulators is usually not necessary but if used, be sure to follow the label.

See the Insect Management Guide for Pantry and Stored Food Pests (<http://edis.ifas.ufl.edu/IG095>) for current management recommendations.

Commercial

The drugstore beetle is a common pest of processed and packaged food products. It is found in flour mills, bakeries, pet food, breakfast cereal manufacturing, and snack food plants, chocolate factories, confectionaries, wholesale distribution centers and sometimes retail stores. Integrated pest management (IPM) programs are often implemented to control infestations at processing, distribution, and storage facilities.

Large-scale control for severe infestations can be achieved by fumigation. However, the use of one fumigant, methyl bromide -- which destroys ozone in the atmosphere -- will be banned in 2005 according to an addition to the Montreal Protocol (an international agreement signed by over 150 countries) in 1995. Heat treatment has been used with limited success. Effective control is obtained when a temperature of approximately 50°C (122°F) is maintained for 24 to 36 hours.

Residual insecticides registered for use on drugstore beetles can be applied to cracks, crevices and shelves in storage areas after removal of stored products (check labels for specific use). Insect growth regulators (IGRs) may be used as part of an IPM program. Sticky traps baited with the female sex pheromone, stegobinone, can be used to monitor for adult beetles. Mass-trapping -- which involves setting out large numbers of traps in infested areas with the intent of catching large numbers of beetles to reduce the population -- has been tried, but effectiveness is limited because only males are attracted to the traps. For mass trapping of drugstore beetles to succeed, a large enough number of males must be caught to ensure that few females will be mated. Pheromone traps are mostly used for detecting and monitoring beetle populations. The traps typically are set out in a grid-like pattern within a facility and monitored at regular intervals for trapped males. If one or more traps in a particular area happen to catch a greater proportion of beetles, then more traps are set out in that area to pinpoint the source of infestation.

Natural Enemies

The drugstore beetle is attacked by a variety of generalist natural enemies. Predators include *Tenebriodes* sp. (Tenebrionidae), *Thaneroclerus* sp. (Cleridae) and several carabids. Eggs may be eaten by predatory mites. Parasitoids include wasps in the families Pteromalidae, Eurytomidae and Bethyilidae. However, biological control for stored-product pests has not been widely adopted. Part of the problem is that although it reduces the amount of pesticides used for control, the release of beneficial insects to control stored-product pests increases the total amount of insects and insect parts in foodstuffs.

Chemical Ecology

The drugstore beetle sex pheromone, stegobinone (2,3-dihydro-2,3,5-trimethyl-6-(1-methyl-2-oxobutyl)-4H-pyran-4-one) is used in commercially available traps and lures. Stegobinone has also been identified as the sex pheromone of a wood-feeding anobiid, the common furniture beetle, *Anobium punctatum*. Wind-tunnel assays in one study revealed that male furniture beetles were attracted to female drugstore beetle extracts. Thus, stegobinone-baited lures can be marketed for two different pest species. Stegobinone has also been tentatively identified as the sex pheromone of two other wood-destroying anobiids from the mid-Pacific coast of North America, *Hemicoleus gibbicollis* and *Ptilinus basalis*.
