Chilli thrips Scirtothrips dorsalis Hood (Insecta: Thysanoptera: Thripidae)\textsuperscript{1}
Vivek Kumar, Dakshina R. Seal and Garima Kakkar\textsuperscript{2}

Introduction
The chilli thrips, Scirtothrips dorsalis Hood, is an important pest of various vegetable, ornamental and fruit crops in southern and eastern Asia, Africa, and Oceania (Ananthakrishnan 1993, CABI/EPPO 1997, CAB 2003).

Synonymy
Anaphothrips andreae Karny 1925
Heliothrips minutissimus Bagnall 1919
Neophysopus fragariae Girault 1927
Scirtothrips andreae (Karny)
Scirtothrips fragariae (Girault)
Scirtothrips minutissimus (Bagnall)
Scirtothrips padmae Ramakrishna 1942

Distribution
Scientists believe that S. dorsalis originated either in Southeast Asia or in the Indian subcontinent, but it is now widely distributed. It is abundant on sacred lotus in Thailand (Mound and Palmer 1981), and on chilli peppers in India (Ramakrishna Ayyar 1932, Ramakrishna Ayyar and Subbiah 1935), where it is also a serious pest of peanuts (Amin 1979, 1980). In Japan, S. dorsalis is a pest of tea and citrus (Kodomari 1978). Scirtothrips dorsalis has been reported from South Africa and the Ivory Coast, and plant quarantine interceptions suggest that this pest is widely distributed across West Africa and is present in East Africa (Kenya).

Due to its diverse vegetation and subtropical climate, Florida is extremely suitable for the establishment of invasive alien flora and fauna (Ferriter et al. 2006). In the United States, the chilli thrips, Scirtothrips dorsalis Hood, is a relatively new, introduced insect pest in Florida and Texas.
Although Venette and Davis (2004) suggested that the potential geographic distribution of *S. dorsalis* in North America might extend from southern Florida north into Canada, a study by Holt (2006) indicates that this species would be troublesome primarily in the southern and Pacific states. These studies signal that it could also become widely established in much of South America, and throughout Central America and Mexico. If this insect becomes widely distributed in the United States it could cause annual crop losses in excess of $3 billion (Holt 2006). According to the Florida Nurserymen and Growers Association, *S. dorsalis* is one of the thirteen most dangerous, exotic pest threats to the ornamental industry (FNGA 2003).

In the United States, USDA-APHIS inspectors at various ports-of-entry have intercepted *S. dorsalis* 89 times since 1984 on imported plant materials belonging to 48 taxa (USDA 2004), and most frequently on cut flowers, fruits and vegetables. In Florida, an infestation of *S. dorsalis* was first reported from Okeechobee County on October 2, 1991, and then from Highlands County on October 10, 1994, with subsequent occurrences in 2004, 2005 and 2007 in various counties of Florida and southeastern Texas.

**Known distribution, hosts, and initial discovery dates of *S. dorsalis* in the Greater Caribbean Region:**

- Jamaica - (1995, 2007, 2008 - However, no major outbreaks as of 2008.)
- Venezuela - grapevines (2000)
- St. Vincent - pepper, amaranth, bean, eggplant, okra, pumpkin, tomato and watermelon; in 8 of 8 districts (as of 2003)
- St. Lucia - pepper, cucumber, eggplant, amaranth - found in 4 of 8 districts (as of 2004)
- Trinidad - pepper, cucurbits, eggplant, okra; in 6 of 8 counties (as of 2004 - not of concern in 2008)
- Texas - roses in landscape, on roses and peppers in retail centers (2005)
- Barbados - sea island cotton, beans, carrots, peppers, eggplant (2005)
- Puerto Rico - mango (2006)

**Identification**

The small size (< 2 mm) of *S. dorsalis* life stages and rapid movement make it difficult to detect this insect in fresh vegetation. The very tiny eggs are inserted into soft plant tissues, and the egg stage may last one week. These characteristics increase the chance of transportation of *S. dorsalis* through international trade of fresh plant materials. *Scirtothrips dorsalis* life stages occur on all the above-ground plant parts of its hosts, and cause scarring damage due to feeding or the transmission of pathogens (Chang et al. 1995, Seal et al. 2006b).

Generally, chilli thrips are pale colored and the lengths of their first and second instar larvae and the pupae are 0.37-0.39, 0.68-0.71 and 0.78-0.80 mm, respectively. Adults are about 1.2 mm long with dark wings and dark spots forming incomplete stripes which appear dorsally on the abdomen (Seal et al. 2009a).

There are numerous microtrichia and dark transverse antecostal ridges on the abdominal tergites as well as sternites. On the lateral microtrichial fields of the abdominal tergites are three discal setae. The posteromarginal comb on segment VIII is complete. The shaded forewings are distally light in color with straight cilia. The forewings possess an incomplete second vein, or a row of setae with two or three irregular setae in the distal half and a complete first vein.

Of eight antennal segments, I-II are pale and III-VIII are dark. Antennal segments III and IV have forked sense cones. The head and legs are pale. There are three pairs of ocellar setae on the head. The third ocellar seta is between the posterior ocelli. The postocular setae are equal in length. The anteroangular, anteromarginal and discal setae on the pronotum are short and nearly equal in length. Posteromarginal seta II is 1.5 times longer and broader than posteromarginal setae I and III (Skarlinsky 2004).

Accurate and rapid identification of a newly introduced invasive pest is the primary requirement for an effective biological control program. More than 100 species in the genus *Scirtothrips* have been reported worldwide. Among these, approximately 10 species are serious threats to agricultural production and vegetation in the United States. Members of the genus *Scirtothrips* can be differentiated from other members of Thripidae by the following features (EPPO 2005):

- Surface of pronotum covered with numerous closely spaced transverse striae
- Abdominal tergites presents (laterally) consisting of numerous rows of parallel placed rows of tiny microtrichia (cuticular hairs on the surface of the wing membrane)
- Sternites possessing marginal setae arising at the posterior margins
- Metanotum (tergum of the metathorax) with median pair of setae emerging close to the anterior margin

**Life Cycle and Biology**

The life cycle stages of *S. dorsalis* include egg, first and second instar larvae, prepupa, pupa and adult. Gravid females insert the eggs inside plant tissues above the soil surface. The eggs are microscopic (0.075 mm long and 0.070 mm wide), kidney-shaped and creamy white in color (Seal et al. 2009a). The eggs hatch between two to seven days, depending upon temperature. Larvae and adults tend to gather near the mid-vein or borders of the host leaf.

The two larval stages are completed in eight to ten days and the pupal stage lasts for 2.6-3.3 days. The life span of chilli thrips is influenced by the host plant species. For example, at 28°C it takes 11.0 days for a first instar larva to progress to the adult stage on pepper plants and 13.3 days on squash plants. The chilli thrips adult’s life span lasts 15.8 days on...
Chilli thrips Scirtothrips dorsalis Hood (Insecta: Thysanoptera: Thripidae)

eggplant, but only 13.6 days on tomato plants (Seal et al. 2009a).

Unlike other thrips, pupae of chilli thrips are generally found on leaves, leaf litter or on the axils of leaves, in curled leaves or under the calyces of flowers and fruits.

Hosts

Before its arrival in the Western Hemisphere, S. dorsalis was known to infest a wide variety of host-plants belonging to more than 100 plant taxa among 40 families (Mound and Palmer 1981). After its introduction into the Western Hemisphere, S. dorsalis was found to attack additional taxa of plants (Klassen et al. 2008, Osborne 2008, Venette and Davis 2004). While their main wild host-plants belong to the pea family (Fabaceae), such as Acacia, Brownea, Mimosa and Saraca, the chilli thrips has also been recorded as a pest of numerous other economically important host plants in various plant families.

Among the potential economically important hosts of this pest in Western Hemisphere listed by Venette and Davis (2004) are banana, bean, cashew, castor, citrus, cocoa, corn, cotton, eggplant, grapes, litchi, longan, mango, melon, peanut, pepper, poplar, rose, strawberry, sweet potato, tea, tobacco, tomato, and wild yams (Dioscorea spp.). Scirtothrips dorsalis is a significant pest of ornamental plantings in Florida.

Plants in Florida on which S. dorsalis is known to reproduce are as follows:

- Antirrhinum majus L. - Liberty Classic white snapdragon
- Arachis hypogaea L. - peanut or groundnut grown in greenhouse
- Begonia sp. - begonia
- Breynia nivosa (W. Bull) Small - snow bush, snow-on-the-mountain
- Capsicum annum L. - pepper
- Celosia argentea L. - celosia, red fox
- Coreopsis sp. - tickseed
- Cucumis sativus L. - cucumber
- Cuphea sp. - waxweed, tarweed
- Duranta erecta L. - golden dewdrop, pigeonberry, skyflower
- Euphorbia pulcherrima Willd. - poinsettia
- Eustoma grandiflorum (Raf.)Shinn. - Florida blue lisanthus
- Ficus elastica 'Burgundy' Roxb. ex Hornem - Burgundy rubber tree
- Fragaria x ananassa - strawberry
- Gaura lindheimeri Engelm. & Gray - Lindheimer’s beebslom
- Gerbera jamesonii H. Bolus ex Hook. f. - Gerber daisy
- Glandularia x hybrida (Grönland & Rümpler) Neson & Pruski - verbena
- Gossypium hirsutum L. - cotton grown in greenhouse
- Hedera helix L. - English ivy
- Impatiens walleriana Hook. f. - super elfin white
- Lagerstroemia indica L. - crape myrtle
- Ligustrum spp. - ligustrum
- Ocimum basilicum L. - sweet basil
- Pelargonium x hortorum Bailey - geranium
- Pentas lanceolata (Forssk.) Deflers - graffiti white
- Petunia x hybrida - petunia easy wave red
- Pittosporum tomentosum (Thunb.) W. T. Aiton - variegated pittosporum
- Plectranthus scutellarioides (L.) R. - coleus
- Plumbago auriculata Lam. - Cape leadwort, plumbago, jamin azul
- Ricinus communis L. - castor bean
- Rhaphiolepis umbellata (Thunb.) Makino - Yeddo hawthorn
- Richardia brasiliensis Gomes - Brazil pusley, tropical Mexican clover, in greenhouse
- Rhododendron sp.
- Rosa sp. - rose
- Salvia farinacea Benth. - victoria blue
- Shefflera arboricola (Hayata) Merr. - umbrella tree
- Tagetes patula L. - marigold
- Tradescatia zebrina hort. ex Bosse - wandering jew
- Vaccinium corymbosum L. - highbush blueberry
- Viburnum odoratissimum var. abwabuki (K. Koch) Zabel - sweet viburnum
- Viburnum suspensum Lindl. - viburnum
- Viola x wittrockiana Gams - Wittrock’s violet
- Vitis vinifera L. - grapevine
- Zinnia elegans Jacq. - zinnia profusion white

(from Klassen et al. 2008, Osborne 2008)

Host list of chilli thrips, Scirtothrips dorsalis among different families of plants

- Actinidiaceae: Actinidia delicosa
- Amaranthaceae: Alternanthera sessilis, Amaranthus spp.
- Anacardiaceae: Anacardium occidentale, Mangifera indica
- Asparagaceae: Asparagus officinalis
- Asteraceae: Dahlia pinnata, Imorphotheca aurantiaca, Helianthus annuus
- Caprifoliaceae: Viburnum awabuki
- Chenopodiaceae: Beta vulgaris
- Convulvulaceae: Ipomoea batatas
- Cucurbitaceae: Citrullus lanatus, Cucumis melo, Cucumis sativus, Cucurbita pepo
- Ebenaceae: Diospyros kaki
- Euphorbiaceae: Hevea brasiliensis, Ricinus communis
- Fabaceae: Acacia auriculiformis, Acacia brownie, Arachis hypogaea, Brownea spp., Dolichos lablab, Glycine max,
Melilotus indica, Mimosa pudica, Phaseolus vulgaris, Saraca minor, Saraca spp., Tamarindus indica, Vigna radiate
- **Hydrangeaceae**: Hydrangea spp.
- **Liliaceae**: Allium cepa, Allium sativum
- **Lythraceae**: Cuphea hyssopifolia
- **Malvaceae**: Gossypium hirsutum
- **Moraceae**: Morus sp.
- **Myrtaceae**: Syzygium samarangense
- **Nelumbonaceae**: Nelumbo lutea, Nelumbo nucifera
- **Passifloraceae**: Passiflora edulis
- **Poaceae**: Zea mays
- **Polygonoaceae**: Fagopyrum esculentum
- **Portulacaceae**: Portulaca oleracea
- **Punicaceae**: Punica granatum
- **Rhamnaceae**: Zizyphus mauritiana
- **Rosaceae**: Fragaria chiloensis, Prunus persica, Pyrus spp., Rosa spp., Rubus spp.
- **Rutaceae**: Citrus aurantiifolia, Citrus sinensis
- **Salicaceae**: Populus deltoids
- **Sapindaceae**: Dimocarpus longan, Litchi chinensis, Nephelium lappaceum
- **Solonaceae**: Capsicum annuum, Capsicum frutescens, Lycopersicon esculentum, Nicotiana tabacum, Solanum melongena, Solanum nigrum
- **Theaceae**: Camellia sinensis
- **Vitaceae**: Vitis pteroclada, Vitis vinifera
(from Holtz 2006)

**Damage**

Thrips possesses piercing and sucking mouthparts and causes damage by extracting the contents of individual epidermal cells leading to necrosis of tissue. This changes the tissue color from silvery to brown or black. Chilli thrips create damaging feeding scars, distortions of leaves, and discolorations of buds, flowers and young fruits by feeding on the meristems of the host plant’s terminals and on other tender parts above the soil surface. *Scirtothrips dorsalis* has not been reported feeding on mature host tissues. According to Sanap and Nawale (1987), adult and nymphs of *S. dorsalis* suck the cell sap of leaves, causing rolling of the leaf upward and leaf size reduction. For example, a heavy infestation of *S. dorsalis* in pepper plants changes the appearance of the plant to what is called “chilli leaf curl.” Appearance of discolored or disfigured plant parts suggests the presence of *S. dorsalis*.

A severe infestation of chilli thrips makes the tender leaves and buds brittle, resulting in complete defoliation and total crop loss. Infested fruits develop corky tissues (Seal et al. 2006b). Sometimes *S. dorsalis* infested plants superficially appear like broad mite infested plant. On many hosts, after a heavy infestation chilli thrips also start feeding on the upper surface of leaves.

![Figure 12. Deformed pepper fruit (no economic value) after damage from an infestation of the chilli thrips, *Scirtothrips dorsalis* Hood. Credits: Vivek Kumar, University of Florida](image12)
Disease Transmission

*Scirtothrips dorsalis* also possesses strong viruliferous behavior for seven recorded viruses. This species transmits chili leaf curl (CLC) virus, and peanut necrosis virus (PBNV) (Mound and Palmer 1981, Ananthakrishnan 1993). In 2003, Rao et al. found chilli thrips as vectors of tobacco streak virus (TSV) in groundnut crops in India. Recently, in Thailand its role as a vector of three tospoviruses (i.e., melon yellow spot virus (MYSV), watermelon silver mottle virus (WsMoV), and capsicum chlorosis virus (CaCV) in field crops was confirmed (Chiemsombat et al. 2008).

Management

Development of effective management practices for *S. dorsalis* is still in its infancy. Many recommendations have been suggested by the World Vegetable Center (AVRDC) which could serve as basic management practices for this pest. Management practices include crop rotation, removal of weeds (which may serve as hosts), and supporting the maximum use of natural enemies, including predators and parasites, and rotating insecticides.

**Chemical control.** Upon the establishment of *S. dorsalis* in the Caribbean in 2003 there was a paucity of information for effective management of this insect with modern insecticides. In order to impede the development of insecticide resistance it is always advisable to use insecticides from different classes in rotation. Pyrethroids have never been reported to provide effective control against *S. dorsalis* (Seal et al. 2006a). Various formulations of imidacloprid used as either soil drench or foliar application provide effective control of *S. dorsalis* without harming natural control agents. Imidacloprid suppresses *S. dorsalis* populations for many days (Seal et al. 2009b). Spinetoram gives the best result when used as a foliar application and imidacloprid as soil drench (Seal et al. 2008). In addition, these two insecticides when applied as above allow the continuous growth and development of natural enemies of *S. dorsalis*.

While the above provides general guidelines, for recommended controls see the University of Florida Chilli Thrips website.

**Biological control.** Various biological control agents, including minute pirate bugs, *Orius* spp. (Hemiptera: Anthocoridae) and entomopathogenic nematodes, *Thripinema* spp. (Tylenchida: Allantonematidae), have been reported to effectively control field populations of the chilli thrips. Adults of *Orius insidiosus* feed on all the life stages of thrips. Because *Orius insidiosus* also feeds on aphids,
mites, moth eggs and pollen, its population does not decline strongly even if thrips populations are drastically reduced. *Thripinema* species are entomogenous nematodes which parasitize female thrips and make them incapable of laying eggs, leading to the reduction of thrips populations. In addition, they also reduce food consumption of these thrips, resulting in limited feeding damage.

Arthurs et al. (2009) evaluated two phytoseiid mites, *Neoseiulus cucumeris* and *Amblyseius swirskii*, as potential biological control agents of the chilli thrips and reported that *Amblyseius swirskii* can be a promising tool in managing chilli thrips on pepper. Other predators of chilli thrips which are being investigated, but on which adequate practical studies to assess their potential as significant natural enemies of thrips have not been done, include:

- lacewings, *Chrysoperla* spp.
- ladybird beetles
- predatory thrips, such as *Frankliniathrips vespiformis* (vespiform thrips), *Scolothrips sexmaculatus* (sixspotted thrips), *Selenothrips rubrocinctus* (redbanded thrips), *Leptothrips mali* (black hunter thrips).
- predatory phytoseiid mites, such as *Amblyseius* spp., *Euseius hibisci* and *Euseius tularensis*.

When used alone, the fungal pathogen *Beauveria bassiana* is not effective in controlling chilli thrips adults or larvae, but produced better result when used in combination with Tricon (an experimental product consisting of borax, orange oil and biodegradable surfactants) (Kumar, unpublished data).
