An Asian Ground Beetle, *Mochtherus tetraspilotus* (MacLeay) (Coleoptera: Carabidae: Lebiini)

Paul M. Choate

Introduction

*Mochtherus tetraspilotus* (MacLeay) was first detected in southern Florida in 1992 from two specimens taken at mercury light by Vince Golia in Palm Beach County. These specimens remained unidentified until 1999 when Danny Shpeley, of the University of Alberta, determined them to be *Mochtherus*. Since then specimens have been collected in Gainesville by Paul Skelley, of the Division of Plant Industry, and Paul Choate, and additional specimens have been seen from light trap samples at Archbold Biological Station in Highlands County.

Description

Length 6 mm to 8 mm. *Mochtherus tetraspilotus* may be distinguished from other Florida Lebiini by a combination of the following characters: hind tarsomere four is not bilobed; tarsal claws with three teeth, a large outer tooth and two smaller inner teeth; mentum toothed; elytral interval three with two dorsal punctures; each elytron with two yellowish orange spots (Figure 1); labial palpi slender; pronotum setulose (covered with short hairs, which are best viewed with side lighting). The most easily observed character is the presence of two yellowish-orange spots on each elytron. A humeral spot extends from intervals four or five to seven or eight, and a subapical spot covers intervals two to five. No other Florida Lebiini species is known with this coloration and combination of characters. Two genera containing maculate species that might be confused with this species are *Plachionus* and *Pinacodera*. However, these genera are separated from *Mochtherus* by their labrum being distinctly wider than long and their head lacking a long seta posterior to the submentum.

Within *Mochtherus* only two species have yellow-orange spots, *Mochtherus tetraspilotus* and *Mochtherus longipennis* Jedlička. They may be separated by the following characters: *Mochtherus tetraspilotus* has pronotum wider than head, oval body shape, with sides rounded; *Mochtherus longipennis* has pronotum only as wide as head, body elongate, sides parallel (Jedlička 1963).

**Biology and Pest Status**

Little is known about the biology of this species. Members of the carabid subtribe Pericalina are known to inhabit the trunks of trees. Darlington (1968) reported a species of *Mochtherus* in New Guinea as occurring on recently felled logs. In Florida, specimens have been collected on recently felled logs where they actively run about, feeding on small insects. Individuals have also been taken at lights. This species occupies the same habitat as a native carabid species, *Coptodera aerata* Dejean. The impact of *Mochtherus* on *Coptodera* remains unknown.

The pest status of this species is unknown at present. Adult members of this group of Carabidae are known to be predators. The impact of this species on our native species remains to be determined, as does the source of introduction. Its rapid spread in Florida suggests that it may soon be found throughout the Gulf States.

**Distribution**

The genus *Mochtherus* is known from Japan, Formosa, Philippines, Borneo, Java, Sumatra, Malaya, Indo-China, Thailand, Burma, Ceylon, India, across the Malay Archipelago, New Guinea, as well as Christmas Island and Samoa. (Habu 1967; Jedlička 1963; Darlington 1968). *Mochtherus tetraspilotus* is known from Japan, Burma, Philippines, Laos, Taiwan, Borneo, Java, Ceylon, and India (Jedlička 1963; Habu 1967). Habu (1967) considered *Mochtherus* a subgenus of *Dolichoctis*.
