Cucumber Production in Miami-Dade County, Florida

Y. C. Li, W. Klassen, M. Lamberts, and T. Olczyk

Situation
Cucumber (for pickling or slicing), a traditional vegetable crop in Miami-Dade County, is grown on annual acreages of 200 to 900 acres. Yields range from less than 300 bushels/acre to more than 600 bushels/acre. Production costs may exceed $8 per bushel or $4,850/acre for an acceptable yield of 600 55-pound bushels. Cucumber produced in Miami-Dade County is sold mainly on the fresh market during winter nationwide.

Varieties
Refer to Table 7.3 in Chapter 7 in the Vegetable Production Handbook of Florida 2017–2018 for variety selection (Freeman et al. 2017, http://edis.ifas.ufl.edu/pdffiles/cv/cv12300.pdf). The major varieties currently grown in the Miami-Dade County for pickling are Eureka, Napoleon, and Transamerica, and for slicing are Speedway, Greensleeves, Dasher II, Thunder, Lightning, and General Lee.

Soils, Land Preparation, and Seeding
Cucumbers in Miami-Dade County are mainly grown on gravelly soils. To be suitable, gravelly soils must be a minimum of 6 inches deep above the bedrock. Periodic rock-plowing increases soil depth and brings the finer soil particles to the surface. Cucumbers are sensitive to flooding. There is a high risk of losing cucumber crops by flooding of low elevation marl soils. Planting on raised beds reduces losses during periods of flooding.

Typically cucumber beds are 36–40 inches wide, 6–8 inches high and spaced 6 ft between the centers of adjacent beds. Preplant fertilizer should be applied in two parallel bands, each about 9 inches from the center of the bed, and incorporated into the soil by rototilling to a depth of 4 to 6 inches. After rototilling, the bed must be re-formed. The bed should be irrigated and kept moist for at least one week to promote the germination of weed seeds. Then, if the bed has become dry, it should be irrigated again one day before the application of a fumigant. Either one or two drip irrigation tubings, 12 to 14 inches apart, are installed in the surface layer, and the bed is immediately covered with plastic mulch.

To allow sufficient time for the fumigant to dissipate completely, cucumber seedlings should not be transplanted into the fumigated bed until at least a week after application of the fumigant. Transplanting season extends from October to late February. Seedlings should be spaced 6–12 inches apart, and set 2–3 inches deep. If seedlings are planted in a “double row” (parallel rows 10–15 inches apart on the same bed), the within row spacing should be the same as in a single row planting.
Fertilizer
Calibrated soil tests for the calcareous soils of Miami-Dade County are not available at present. Before the tests are available, you may refer to Chapter 2 in the Vegetable Production Handbook for Florida 2017–2018 (Liu et al. 2017, http://edis.ifas.ufl.edu/cv296). More practically, tissue analysis is recommended for determining the composition and rates of fertilizers to be applied. Instructions for tissue sample collection, preparation and submission are provided in Plant Tissue Information Sheet (Mylavarapu et al. 2017, http://edis.ifas.ufl.edu/ss182), which is available from your local UF/IFAS Extension office. Information on plant tissue analysis for cucumber is provided in the Vegetable Production Handbook of Florida 2017–2018 (Freeman et al. 2017, http://edis.ifas.ufl.edu/pdffiles/cv/cv12300.pdf). The total amount of fertilizer required in Miami-Dade County depends on the variety, soil fertility, and other environmental factors. Less inorganic fertilizer should be applied if a cover crop or soil organic amendment (compost, biosolids, manure) has been applied. Pre-planting fertilizer formulas of 6-6-6, 6-3-6, 10-10-10, or similar formulas are satisfactory. Less than one-half of the fertilizer (N, P, or K or all) should be applied to the beds prior to planting. Fertigation should be initiated with a 4-0-8 or similar formula 3-4 weeks after transplanting to provide the remaining fertilizer. The beds should be fertigated once or twice a week with daily rates ranging from 0.5 lb N to 2 lb N per acre. Magnesium nitrate or sulfate and EDDHA-chelated iron (Liu et al. 2015, http://edis.ifas.ufl.edu/hs1208) should be applied if the soil-test report shows low. Please also refer to Chapter 2 in the Vegetable Production Handbook for Florida 2017–2018 (Liu et al. 2017, http://edis.ifas.ufl.edu/cv296).

Insect Management
Refer to Chapter 7 in the Vegetable Production Handbook of Florida 2017–2018 (Freeman et al. 2017, http://edis.ifas.ufl.edu/pdffiles/cv/cv12300.pdf) for extensive information on insect control. The major pests of cucumber are the melon thrips, melonworm, pickleworm, and spidermites.

Disease Management

Weed Management

Harvest
Cucumbers (slicers and pickles) produced in Miami Dade County are used mainly for the domestic market. The harvest season extends from October through mid-December and from February through June. Cucumbers are hand-picked.

Multiple Cropping/Rotation
Cucumber can be rotated with tomato, eggplant, pepper, herbs, or squash. However there is risk in rotating cucurbits with solanaceous crops because of Phytophthora blight. This disease is caused by Phytophthora capsici, which develops explosively in moist conditions and produces large numbers of infective sporangia. The disease is very damaging and difficult to control.
