Predatory Stink Bug, *Stiretrus anchorago* (Fabricius) (Insecta: Hemiptera: Pentatomidae)\(^1\)

David B. Richman and Frank W. Mead\(^2\)

**Introduction**

*Stiretrus anchorago* (Fabricius) is a medium-sized predatory stink bug which preys on both coleopterous and lepidopterous larvae and has been taken on soybeans, peanuts, alfalfa, and corn. It is predatory on the larvae of the *Mexican bean beetle*, *Epilachna varivestis* Mulsant (Howard and Landis 1936; Waddill and Shepard 1974, 1975; Deitz et al. 1976) the alfalfa weevil, *Hypera postica* (Gyllenhal) (Richman 1977), and at least one lepidopterous species, *Eurema nicippe* (Cramer) (Richman and Whitcomb 1978). In the laboratory, it has been successfully reared on larvae of the Mexican bean beetle (Waddill and Shepard 1974, 1975), the cabbage looper, *Trichoplusia ni* (Hubner), and the soybean looper, *Pseudoplusia includens* (Walker) (Richman and Whitcomb 1978).

**Life Cycle**

At 26 to 27°C and a light to dark photoperiod of 14:10, the time from egg to adult was 25 to 35 days. The egg stage lasted six to seven days (Waddill and Shepard 1974; Richman and Whitcomb, 1978).

**Identification**

The genus is recognized easily by the enlarged long and broadly oval scutellum, approaching that of scutellerids; subapical spine on the front femora; and ventral pubescent patches on the males. Hayslip et al. (1953) illustrated color variations of the adults. DeCoursey and Allen (1968) provided a generic key that is useful in separating 5th instar nymphs, but several Florida genera were not included. Only one highly variable species of *Stiretrus* occurs in the United States. Under the name of *Stiretrus fimbriatus* (Say), Oetting and Yonke (1971) provided illustrations, detailed descriptions, life history, and biological notes. Most authors consider *S. fimbriatus* as no more than a subspecies or color variant of *S. anchorago*. R.I. Sailer (personal communication, 1979) also believes *S. fimbriatus* to be a color variant of *S. anchorago* collected most frequently in the northern range of the species.

**Eggs**

The ellipsoidal, blackish eggs of *S. anchorago* are approximately 1 mm in diameter with short projections around the operculum. These are laid in two rows containing a few eggs to nearly 30.

Larvae

1st instar
Length approximately 1.5 mm; head width, including eyes, 0.7 mm; humeral width 1.0 mm. The 1st instar nymphs of *S. anchorago* are more globose than the 1st instar nymphs of most other species. At hatching the nymphs are red, but they soon turn black. They resemble tiny black beetles at this time and do not feed though they do require water in some form.

2nd instar
Length 2.0 to 2.5 mm; head width 0.9 mm; humeral width 1.4 mm. As in other asopine stink bugs, *S. anchorago* begins to take prey as a 2nd instar nymph. The color of the nymph is blackish blue. The nymph is very globose and assumes the predatory habit, though they may on occasion feed on plant tissue.

3rd instar
Length 3.0 to 3.5 mm; head width 1.2 mm; humeral width 2.1 mm. The 3rd instar does not differ much from the 2nd instar nymph, except in size.

4th instar
Length approximately 4.5 mm; head width 1.6 mm; humeral width 3.0 mm. Again the 4th instar nymph resembles the 3rd instar, except in size.

5th instar
Length 7.0 to 8.0 mm; head width 2.1 mm; humeral width 4.4 mm. The 5th instar nymph may be either all blackish blue or may have varying degrees of red markings on the pronotum. The red markings are, however, not related to the adult pattern, and red-marked nymphs may become solid-colored adults.
Predatory Stink Bug, *Stiretrus anchorago* (Fabricius) (Insecta: Hemiptera: Pentatomidae)

**Adult**

Male length 7 to 8 mm; head width 2.2 mm; humeral width 5.6 mm. Female length 8-9 mm; head width 2.3 mm; humeral width 6.2 mm. Adults of *S. anchorago* are quite variable in appearance. Some specimens are solid iridescent blue, green or purple, while others are patterned with orange or red and in the *fimbriatus* form with cream color. The coloration is not related to sex.

**Survey and Detection**

- It has been collected throughout the year in Florida, but is more common in the warmer months.
- It is most apt to be found on soybeans, pole beans, potatoes, and other truck and row crops where its prey of beetle larvae and caterpillars abound.
- Specimens can be collected by hand or net and submitted for identification in alcohol-filled vials or dry in pill boxes.
