Harvester Butterfly, *Feniseca tarquinius* (Fabricius) (Insecta: Lepidoptera: Lycaenidae: Melitinae)\(^1\)

Donald W. Hall, Jerry F. Butler, and Marc Minno\(^2\)

---

**Introduction**

The larvae of the small, uncommon harvester butterfly, *Feniseca tarquinius* (Fabricius), are the only strictly carnivorous butterfly caterpillars in the United States.

**Distribution**

Found in swampy areas and woodlands, particularly near water, from southern Canada south to central Florida and central Texas. Highly localized with adults generally remaining in close proximity to woolly aphid hosts.

**Description**

**Adults**

The wings are orange on the interior, bordered with black on the dorsal surface and burnt-orange with darker spots edged with white on the ventral surface (Figure 1).

**Eggs**

The eggs are greenish-white and spherical with faint sculpturing (Figure 2).

**Larvae**

The larvae (Figures 3–5) are small (to 1.9 cm in length) and slug-like. Full-grown larvae are brightly patterned with gray, yellow and white, and covered with bristly hairs; the pattern is often obscured with the white wax produced by the prey (Minno et al. 2005).

**Pupae**

The pupae are off-white and have a pattern that resembles the face of a lizard or monkey (Krizek 1995) (Figure 6).

Life Cycle and Biology

There are two to three generations in Canada and the northern US and from three to six generations in the southern US. Eggs are laid singly on leaves or stems near colonies of the woolly aphid prey. Caterpillars are present from June in the North and from February through early November in Florida.

Overwintering is by the pupal (chrysalis) stage (Allen 1997).

Because the harvester caterpillar is carnivorous, development proceeds very rapidly, with the larval stage being completed in as little as eight days. Harvester larvae have only four larval instars. Most other butterflies have five
First instar larvae may restrain their larger aphid prey with silk prior to attacking them (D.W. Hall, unpublished observations).

Some harvester caterpillars cover themselves with the remains of woolly aphids they have eaten. The carcasses are tied on with silk, perhaps to protect the caterpillars from predacious ants (that tend and protect the aphids) and other natural enemies. Harvester caterpillars are less likely to conceal themselves when their woolly aphid prey is tended by *Camponotus* and *Formica* ants (Youngsteadt and Devries 2005).

Lohman et al. (2006) reported that the caterpillars share part of the cuticular hydrocarbon profile of the aphids and may be protected from the aphid-attending ants and protected by the ants from other predators by this chemical mimicry. Although harvester larvae lack the secretory and call-production organs of other ant-attended lycaenids (Youngsteadt and Devries 2005), they are sometimes attended by ants (Wagner 2005). Interestingly, harvester pupae do have well-developed stridulatory organs (Douglas 1986). The function of these organs in the pupae is not known.

The proboscis of harvester adults is very short, and they do not feed on floral nectar. Instead, they feed on aphid honeydew, dung, sap, and also sip from mud (Scott 1986). Because the adults are small in size, spend most of their time in the locality of their aphid prey, have an erratic flight, and do not feed at flowers, they are not commonly seen. Therefore, they are probably perceived as being more uncommon than they actually are (Wagner 2005).

**Hosts**

Harvester larvae are predacious on woolly aphids of at least five genera: *Meliarhizophagus, Neoprociphilus, Pemphigus, Prociphilus,* and *Schizoneura* (Iftner et al. 1992, Minno et al. 2005, Scott 1986, Opler and Krizek 1984); and possibly on other Homoptera.

The common prey species in Florida are woolly maple aphids, *Neoprociphilus aceris* (Monell) (Figure 7), that suck sap from earleaf greenbriar (*Smilax auriculata* Walter), saw greenbriar (*Smilax bona-nox* L.), cat greenbriar (*Smilax glauca* Walter), and bristly greenbriar (*Smilax tannoides* L.), in the smilax family (Smilacaceae); as well as woolly alder aphids, *Prociphilus tesselatus* (Fitch) (Figure 8) (formerly *Paraprocihiphus tesselatus* Fitch) that feed on hazel alder (*Alnus serrulata* (Aiton)Willd.), in the birch family (Betulaceae) (Minno et al. 2005).
