

Facts About Fluoride¹

Anne Kendall and Linda B. Bobroff²

Why do we need fluoride?

Fluoride is important for healthy bones and teeth. It increases the density of bones and also can stimulate the growth of new bone. Fluoride increases the amount of minerals in our teeth and even can reverse the progression of dental cavities (also called caries).

What happens if we do not get enough fluoride?

People who don't get enough fluoride have much greater rates of dental decay and cavities than those who get enough fluoride. Due to water fluoridation, almost one-half of American children have never had a cavity in their permanent teeth.

Because of this success, water fluoridation has been called one of the ten great public health achievements of the twentieth century. Water fluoridation is especially important for children who do not have access to dental care. Recent research indicates that topical use of fluoride in toothpaste may be sufficient to prevent dental cavities. Groups at increased risk for developing dental cavities are those with lower incomes or less education with limited access to dental care.

We must get enough vitamin D and calcium in our diets so that fluoride can be incorporated into our teeth and bones. For information about these two important nutrients, see FY207/FCS8640 *Facts About Vitamin D* (<http://edis.ifas.ufl.edu>).

How much fluoride do we need?

Table 1. Dietary Reference Intakes for Fluoride

Life Stage	Amount
Children 6–12 mos.	0.5 mg*
Children 1–3	0.7 mg
Children 4–8	1.0 mg
Children 9–13	2.0 mg
Children 14–18	3.0 mg
Men, ages 19+	4.0 mg
Women, ages 19+	3.0 mg
Pregnant or lactating women	3.0 mg

*mg = milligrams

How can I get enough fluoride?

Tap water has become the primary source of fluoride in the United States because of the increased fluoridation of community water supplies. Frequent use of topical agents such as toothpastes and mouthwashes containing fluoride are important for maintaining high dental fluoride concentrations. Children and adults at high risk for dental cavities may benefit from additional sources of fluoride such as mouth rinses, topical gels, or dietary supplements, and should check with their doctor for recommendations.

Check with your local water company for the amount of fluoride in your drinking water. If you have a home water filtration system, be sure to check with the manufacturer because many systems may remove fluoride from tap water. Also, if you frequently drink bottled water, be aware that most brands do not contain added fluoride.

Most foods contain little fluoride. Foods usually contribute only 0.3–0.6 milligrams of fluoride each day. Fish eaten with the bones, such as canned sardines or canned salmon, are higher in fluoride than most other foods. A three-ounce serving of canned sardines has about 0.3 milligrams of fluoride. An eight-ounce glass of brewed tea may contain 0.2–1.4 milligrams of fluoride, depending on the source of water used.

How much is too much?

Children who get too much fluoride will have teeth that look stained or “mottled.” This is cosmetic and has no effect on the health of the teeth. Children should be taught to brush properly and to never swallow toothpaste, mouthwash, or fluoride rinses.

Very high intakes of fluoride for periods greater than 10 years can cause pain and stiffness in joints. It also causes abnormal hardening of the bones that can result in fractures. The upper limit for fluoride for children older than eight years and adults is 10 mg/day.

Where can I get more information?

Your local UF/IFAS Extension Family and Consumer Sciences (FCS) agent may have more information or nutrition classes for you to attend. Also, a registered dietitian (RD or RDN) can provide reliable information.
