

# Beans, Peas, and Lentils: Health Benefits<sup>1</sup>

Lakshmi Mahan, Lauren Foster, and Wendy J. Dahl<sup>2</sup>

## Bean Basics

Bean, peas, and lentils are known collectively as legumes or pulses. Beans are great sources of many nutrients, including protein, fiber, and potassium.

Beans, peas, and lentils can be placed either in the vegetable group or the protein group of MyPlate, the food groups that the building blocks of a healthy diet (<http://www.choosemyplate.gov/index.html>). The food group you decide to place beans, peas, and lentils in depends on how successful you have been in meeting the suggested servings for the two groups. If you have consumed enough protein choices, then you can count beans, peas, and lentils in the vegetable group, and vice versa. For example, vegetarians, especially vegans, tend to consider legumes as their primary protein source. Meat eaters may choose to count legumes as vegetables because obtaining sufficient protein through meats and dairy is rather easy.

## Beans, Peas, Lentils, and Nutrition

The fat content of beans, peas, and lentils is generally very low, and there is no cholesterol. Protein content is high, more than the amount of protein that is found in cereal grains (USDA 2015). Obtaining protein from legumes is a healthy choice.

Another important component of beans, peas, and lentils is fiber. Fiber is a part of plant foods that cannot be digested. Beans, peas, and lentils have about 7 g of dietary fiber in a 1/2-cup serving and are especially high in insoluble fiber

(USDA 2015). Insoluble fiber bulks stool and decreases transit time through the colon, thereby preventing constipation. The soluble fiber in beans, peas, and lentils is highly fermentable in the colon, which is thought to be health enhancing. However, fermentation also produces some gas (flatulence) that may cause discomfort for some individuals. Enzyme preparations containing alpha-galactosidases may prevent some of the gas production.

Beans, peas, and lentils are also rich sources of some vitamins and minerals, such as folate, iron, potassium, and magnesium (USDA 2015). Folate and iron are important for preventing anemias, as well as maintaining many normal metabolic functions. Potassium and magnesium are important for muscle and nerve function.

## Health Benefits

### Cardiovascular Disease

Cardiovascular disease is the leading cause of death in the United States, as well as many developed countries (CDC). As processed meat and red meat are associated with an increased risk of cardiovascular disease (Abete et al. 2014), choosing legumes in place of some meat may benefit health and improve overall diet quality (Mitchell et al. 2009). In the Dietary Guidelines for Americans 2015–2020, it is recommended that we consume 1.5 cups of legumes each week. Research has shown that consumption of beans may reduce heart disease risk (Afshin et al. 2014).

## Cancers

Cancer is the second leading cause of death in the US (CDC). Consuming legumes (including soybean) is linked to a lower risk of colorectal cancer (Zhu et al. 2015) and prostate cancer (Diallo et al. 2016). The dietary fiber found in beans, peas, and lentils may help to reduce the risk of certain types of cancer (Dahl and Stewart 2015). Beans, peas, and lentils also contain significant levels of antioxidants and phytochemicals, which are substances associated with preventing chronic diseases like cancer (Sanchez-Chino et al. 2015).

## Diabetes

The glycemic index (GI) is a scale that ranks foods based on how they raise blood glucose levels compared to glucose (a sugar). Beans, peas, and lentils are foods that typically have a lower GI (Mudryj, Yu, and Aukema 2014). Low-GI foods provide a slower release of glucose into the blood, and thus, decrease after-meal peaks in blood glucose levels. For people who have diabetes or are at risk of developing diabetes, low-GI foods are good choices (Wang et al. 2014). The fiber in beans, peas, and lentils may help slow the rate of digestion of the starch and absorption of glucose, which helps regulate blood glucose levels.

## Celiac Disease

Individuals with celiac disease must follow a lifelong diet free of gluten. Gluten is a common name for certain proteins in wheat and wheat-related grains such as rye, barley, triticale, and spelt. Beans, peas, and lentils are gluten free and are an excellent starchy alternative to these foods, allowing people with celiac disease to also consume adequate amounts of fiber.

## Where Can I Get More Information?

The family and consumer sciences agent at your county UF/IFAS Extension office may have more information and nutrition classes for you to attend. Also, a registered dietitian can provide you with reliable information. If you have concerns about your specific health condition, speak to your doctor.
