Little Metalmark, *Calephelis virginiensis* (Guérin-Ménéville) (Insecta: Lepidoptera: Riodinidae)

Donald W. Hall, Jerry F. Butler, and Marc Minno

**Introduction**

The little metalmark, *Calephelis virginiensis* (Guérin-Ménéville), is one of three allopatric metalmarks found in the eastern United States. Although the little metalmark is one of our tiniest butterflies, it is one of our most beautiful. It is the only metalmark found in the southeastern coastal plain.

**Distribution**

Southeastern coastal plain from southeastern Virginia to eastern Texas in uplands and marginal wetlands, sandhills, flatwoods, pine savannas, prairies, and on roadsides.

**Description**

**Adults**

The wings vary in color from rusty orange to orange-brown and have metallic silver lines on the wings (Figure 1)—the characteristic from which the family gets the common name “metalmarks”. The wingspan is 12–25 mm.

**Eggs**

The flattened eggs are reddish-brown with white sculpturing (Figure 2).

**Larvae**

Caterpillars are light-green, stippled with many tiny white dots. There are dorsal and lateral rows of long white setae on each side and a rust-brown sub-dorsal spot on each side on abdominal segments two through seven (Figures 3 and 4).

**Pupae**

The pupae are green with dorsal and lateral rows of black spots (Figure 5). The pupa is covered with setae from the

last instar larva—possibly for protection from predators or parasitoids.

**Life Cycle and Biology**

This metalmark is common throughout Florida, except for the Keys. At least three generations are produced each year in northern parts of its range and multiple generations occur year-round in Florida (Scott 1986). It is most common during late summer and fall in Florida, but caterpillars are present from March through November (Minno et al. 2005).

Little metalmarks are low-flying and are not commonly seen until they land and rest with their wings outstretched. Adults tend to orient themselves in an upside-down position when resting. Males patrol for females but their patrolling is fairly localized. Flat-flowered composites (Asteraceae) seem to be the preferred nectar sources. Eggs are laid singly on the underside of the host leaves. Caterpillars feed mostly at night (Cech and Tudor 2005) on the undersides of the leaves, but leave the translucent upper cuticle intact. These small circular windows in the leaves are a good sign to look for when searching for the caterpillars. Partly grown caterpillars are probably the over-wintering stage (Opler and Krizek 1984).

**Hosts**

Little metalmark caterpillar host plants are herbs in the Aster Family (Asteraceae) including yellow thistle, *Cirsium horridulum* Michx. (Figures 6 and 7), vanillaleaf, *Carphophorus odoratissimus* (J.F.Gmel.) H.Hebert (Minno et al. 2005, Wagner 2005) and sometimes climbing hempvine, *Mikania scandens* (L.) Willd. (Figure 8) (Minno et al. 2005). Caterpillars are especially cryptic on the undersides of the leaves of yellow thistle where their hairs blend in with the long white hairs of the plant.
Yellow thistle flowers vary in color and may be white, yellow, or purple.

Photographs of vanillaleaf are available at the Institute for Systematic Botany (University of South Florida).
