

External Parasites of Sheep and Goats¹

P. E. Kaufman, P. G. Koehler, and J. F. Butler²

Arthropod pests limit production in the sheep and goat industry in many ways. External parasites feed on body tissue such as blood, skin, and hair. The wounds and skin irritation produced by these parasites result in discomfort and irritation to the animal. Parasites can transmit diseases from sick to healthy animals. They can reduce weight gains and milk production. In general, infested livestock cannot be efficiently managed to realize optimum production levels.

Lice

Lice are external parasites which spend their entire lives on the sheep or goat. Both immature and adult stages suck the blood or feed on the skin. Goat lice are host specific and only attack goats and their close relatives, such as sheep.

Louse-infested animals may be recognized by their dull, matted coat or excessive scratching and grooming behavior. Sucking lice pierce the host's skin and draw blood. Biting lice have chewing mouthparts and feed on particles of hair, scab and skin exudations. The irritation from louse-feeding causes animals to rub and scratch, causing raw areas on the skin or loss of hair. Weight loss may occur as a result of nervousness and improper nutrition. Milk production is reduced about 25 percent. Also, the host is often listless and

in severe cases the loss of blood to sucking lice can lead to anemia.

Lice are generally transmitted from one animal to another by contact. Transmission from herd to herd is usually accomplished by transportation of infested animals, although some lice may move from place to place by clinging to flies (phoresy). Lice are most often introduced to herds by bringing in infested animals.

Louse populations vary seasonally, depending largely on the condition of the host. Most sucking and biting lice begin to increase in number during the fall and reach peak populations in late winter or early spring. Summer populations are usually minimal, causing no obvious symptoms. Animals under stress will usually support larger louse populations than normally found.

Control of louse infestations is needed whenever an animal scratches and rubs to excess. Louse control is difficult since pesticides do not kill the louse egg. Since eggs of most species will hatch 8 to 12 days after pesticide application, retreatment is necessary 2 weeks after the first pesticide application.

There are 4 kinds of biting lice and 5 kinds of sucking lice that can attack sheep and goats in Florida.

Biting Lice

Bovicola crassipes (the Angora-goat-biting louse) and *Bovicola limbata* are the two major species of biting lice. *Bovicola caprae* and *Bovicola ovis* (goat-biting louse and sheep-biting louse) are of lesser significance.

All four species live on the skin surface feeding on bits of hair and other skin surface debris. Egg hatch requires 9 to 12 days, and the entire life cycle averages 1 month. The biting lice of goats are world-wide in distribution with winter-time populations being most severe. In Florida high populations have been observed year round.

The best control of biting lice is an animal residual spray. Retreatment is recommended 2 weeks after the first pesticide application for most insecticides.

Sucking Lice

Five species of sucking lice attack sheep and goats. The following are of importance:

1. **African blue louse**—Found in semi-tropical climates in the United States, India, and Puerto Rico. They are found on the body, head, and neck. Heavy populations have caused the death of the host.
2. **Foot louse**—This louse prefers the feet and legs of goats and sheep. Populations peak in the spring, and at that time the lice may affect the belly area as well. Scrotum infestations on bucks are common. Lambs seem to have the highest infestations. Egg hatch for this species of louse takes longer than the other species. Therefore, retreatment should be applied after 3 weeks for most insecticides.
3. **Goat-sucking louse**—Populations are dispersed over the animal's body. These lice are also found on sheep.
4. **The face and body louse and the long-nosed cattle louse**—These are minor pests.

Nose Bot Fly

The nose bot fly infests the nostrils of sheep and goats. In infested animals, there is a discharge from the nostrils, biforous shaking of the head, loss of appetite and grating of the teeth. In the presence of the adult fly, the animals are excited, shake their heads, snort and rush with their noses in the dust.

Nose bot flies are a winter-time problem. Up to 25 bots have been found in the nasal passages of sheep in Florida.

They may cause eye damage in humans. The larvae of the fly are laid in the nostrils. They migrate up the nasal passages and feed on mucous and mucous membranes. Currently, an ivermectin oral drench is the only available treatment.

Keds

Keds (Hippoboscidae), also known as louse flies, are large, flattened, usually wingless parasitic flies. Two species feed on goats, but one reproduces on deer and feeds on sheep.

Sheep ked bites cause irritation and prompt the infested animals to rub, bite, and scratch. They may also roll on the ground in an attempt to relieve irritation.

Keds usually do not cause great damage if the animal is fed on a highly nutritious diet, but sheep grazed throughout the year on pasture or range may acquire heavy burdens of keds during winter and early spring.

Eggs are retained and hatch within the body of the female ked and develop into fully grown larvae ready to pupate. These larvae are then glued to hairs of the host. A female ked is capable of developing only one larva at a time. During the female's life of 100 to 130 days, she produces around 10 to 15 young, giving birth every 8 to 9 days. The pupal stage lasts from 18 to 30 days.

Infestations of Fly Maggots

Fly maggot infestation, *Myiasis*, is the presence of fly larvae in the living host. Several kinds of maggots infest the wounds of warm-blooded animals; however, the only one that feeds exclusively on live flesh is the primary screw-worm. Sterile male releases have irradiated the primary screwworm fly from the Southeast, but there is constant danger of reinfestation.

Other species, such as the secondary screwworm and other blow flies, may also infest wounds. These species normally lay their eggs on carcasses of dead animals and may occasionally occur in open wounds. Although these species may cause worry, they will not consume living flesh and will feed only on dead flesh and wound secretions. Infestations of secondary screwworm often follow an injury which produces untreated wounds or management practices which allow animals to develop bacterial skin infestations. These problems must be cleared up to prevent secondary screwworm infestation.

There is no simple way to differentiate between primary screwworm and other fly larvae. **Any suspected screw-worm case should be reported to the county Extension**

director. Samples of eggs and maggots should be saved in a small container filled with a 70% alcohol solution.

Mites

Itch or mange mites (*Psoroptes*, *Sarcoptes*) feed on the surface or burrow within the skin, making very slender, winding tunnels from 0.1 to 1 inch long. The fluid discharged at the tunnel openings dries to form nodules. A toxin is also secreted which causes intense irritation and itching. Infested animals rub and scratch continuously. Infestations are contagious, and treatment of all animals in a herd is essential to achieve control. Delayed egg hatch requires retreatment at 10 days.

The most common mange of sheep and goats is Psoroptic ear mite (*Psoroptes caniculi*) or scab mite. It lives in the auditory canal and temporarily on the body.

Fleas (*Siphonaptera*)

Fleas are small, wingless insects varying from 1.0 to 8.5 mm in length. They are narrow insects compressed on the sides with spines directed backwards.

Most species move about a great deal and remain on the host only part of the time to obtain a blood meal. The legs are well developed, and they can jump as far as 7 to 8 inches.

The flea has 4 life stages: egg, larva, pupa, and adult. Under favorable conditions, a generation can be completed in as little as 2 to 3 weeks. Mating takes place on the host and eggs are laid on the host. Since they are not attached, the eggs drop to the ground and hatch in from 2 days to several weeks. Development occurs most commonly in the bedding of the resting area of the host.

The larvae are very small, worm-like, legless insects with chewing mouthparts. In several weeks they go through 3 larval stages, feeding on organic debris. The pupal stage lasts approximately one week, then the newly emerged adult flea is ready to feed on blood within 24 hours.

The sticktight flea is the most common flea on sheep and goats. It attaches firmly to its host, usually about the face and ears. This species remains attached to its host for as long as 2 to 3 weeks. During this time eggs are laid. They drop to the ground and hatch into larvae. Large populations of this flea may cause ulcers on the head and ears. Flea infestations often spread to other animals including humans.

External Parasite Control Recommendations for Dairy Goats

Very few pesticides are registered for control of parasites on dairy goats. Read all warnings, directions, and precautions carefully to insure proper usage.

Keys to Pesticide Safety

1. Before using any pesticide, stop and read the precautions.
2. Read the label on each pesticide container before each use. Heed all warnings and precautions.
3. Store all pesticides in their original container away from food or feed.
4. Keep pesticides out of the reach of children, pets, and livestock.
5. Apply pesticides only as directed.
6. Dispose of empty containers promptly and safely.

These recommendations are guidelines only. The user must insure that the pesticide is applied in strict compliance with label directions.

The Food and Drug Administration has established residue tolerances for certain insecticides in the meat and milk of certain animals. When these and other approved insecticides are applied according to recommendations, the pests should be effectively controlled and the animals' products will be safe for use as food.

The improper use of insecticides may result in residue in milk or meat. Such products must not be delivered to processing plants.

To avoid excessive residues, use the insecticides recommended at the time recommended and in the amounts recommended. Remember that goats are smaller animals than cattle and require proportionately less pesticide for adequate treatment. Be careful not to over treat animals. Spray with enough pressure to penetrate the hair coat and wet the skin. Less than 1 quart of spray should be enough to produce complete coverage per animal.

Locating an Approved Pesticide

In 2014, a group of livestock entomologists, as a part of Multi-State Hatch Project S-1060, developed an online system for obtaining the names of registered pesticides

appropriate for use with livestock and pets. This is a state-specific database (only certain states are represented, and Florida is one of these); if you are in another state, you must be certain that your state is represented in the dropdown list.

This database is easily searchable by the type of animal or site that you want to treat (such as a barn), as well as the targeted pest. From these two selections, you can then choose the “Method of Application” and the “Formulation Type.” To use this system, please visit the following URL: http://veterinaryentomology.ucr.edu/vet_pesticides.html.

Although we continuously strive to keep this database current, it is ultimately your responsibility to ensure that the product that you choose is registered in Florida (and the application is made in Florida) and that you use the product in accordance with the label requirements and local laws and ordinances. Remember, “the label is the law” for pesticide use, and the uses indicated on the label, including the site of application and targeted pest(s) must be on the label.

If you have any challenges with this system, please contact your local UF/IFAS Extension Office (<http://sfyl.ifas.ufl.edu/find-your-local-office/>) or for additional assistance contact Dr. Phillip Kaufman, pk Kaufman@ufl.edu.
